Bursa Market Primer

Plain-language starter material for new joiners

Purpose and status

This controlled source was created for the BursaIQ Stage 02 competition prototype. All examples are invented. Replace it only with material approved for the demonstration environment.

1. What an exchange does

An exchange brings together investors and issuers within an organised market. It provides listing, trading, clearing and market-information services under applicable rules.

BursaIQ should help a new joiner understand a term while keeping the original source one click away.

2. Average Daily Value (ADV)

ADV is total traded value divided by the number of trading days in the measurement window. Always name the window because a 30-day ADV and a monthly ADV may differ.

Worked synthetic example: RM68.4 billion traded over 20 trading days gives RM3.42 billion ADV.

3. Market capitalisation

Market capitalisation is the market value of listed securities. At company level it is commonly price multiplied by issued shares. At market level the eligible company values are aggregated.

4. Trading velocity

Trading velocity relates annualised trading value to market capitalisation. It indicates activity relative to market size; it does not by itself prove liquidity quality.

5. Index attribution

Index attribution estimates how constituents or sectors added to or detracted from the index move. Results depend on the index method, constituent weights and reporting cut-off.

6. Investor participation and net flow

Participation share shows how much traded value came from an investor group. Net flow is purchase value less sale value. Aggregated figures should avoid disclosing investor identity.
